Abstract

Consider a periodic Schrödinger operator in two dimensions, perturbed by a weak magnetic field whose intensity slowly varies around a positive mean. We show in great generality that the bottom of the spectrum of the corresponding magnetic Schrödinger operator develops spectral islands separated by gaps, reminding of a Landau-level structure.

Spectral gaps for periodic Hamiltonians in slowly varying magnetic fields

1. The Problem
2. Main Steps of the Proof
3. The magnetic $\Psi D$ calculus for slowly variable symbols.
4. Magnetic almost-Wannier Functions
5. The Feshbach type argument
6. The magnetic quantization of the magnetic quasi Bloch function
7. The resolvent of $\mathcal{D} p^{\epsilon, \kappa}(\lambda^\epsilon)$
The Problem
The periodic Hamiltonian.

- On the configuration space $\mathcal{X} := \mathbb{R}^2$ we consider a lattice $\Gamma \subset \mathcal{X}$ generated by two linearly independent vectors $\{e_1, e_2\} \subset \mathcal{X}$.
- We also consider a smooth, $\Gamma$-periodic potential $V : \mathcal{X} \to \mathbb{R}$.
- Let us fix an elementary cell:

$$E := \left\{ y = \sum_{j=1}^{2} t_j e_j \in \mathbb{R}^2 \mid -1/2 \leq t_j < 1/2, \; \forall j \in \{1, 2\} \right\}.$$

- We consider the quotient group $\mathcal{X} / \Gamma$ that is canonically isomorphic to the 2-dimensional torus $\mathbb{T}$.
- Consider the differential operator $-\Delta + V$, which is essentially self-adjoint on the Schwartz set $\mathcal{S}(\mathcal{X})$. Denote by $H^0$ its self-adjoint extension in $\mathcal{H} := L^2(\mathcal{X})$ with domain the Sobolev space $H^2(\mathcal{X})$. 
The Bloch-Zak representation.

- The dual basis \( \{ e_1^*, e_2^* \} \subset \mathcal{X}^* \) is defined by \( \langle e_j^*, e_k \rangle = (2\pi)\delta_{jk} \), and

\[ \Gamma_* = \bigoplus_{j=1}^2 \mathbb{Z} e_j^*, \quad \mathbb{T}_* := \mathcal{X}^*/\Gamma_*, \]

\[ E_* := \left\{ \theta = \sum_{j=1}^2 t_j e_j^* \in \mathbb{R}^2 \mid -1/2 \leq t_j < 1/2, \ \forall j \in \{1, 2\} \right\}. \]

- The map

\[ (\mathcal{V}_\Gamma \varphi)(\theta, x) := |E|^{-1/2} \sum_{\gamma \in \Gamma} e^{-i<\theta, x-\gamma>} \varphi(x-\gamma), \quad \forall (\theta, x) \in \mathcal{X} \times E_*, \forall \varphi \]

(\text{where } |E| \text{ is the Lebesgue measure of the elementary cell } E) \text{ induces a unitary operator } \mathcal{V}_\Gamma : L^2(\mathcal{X}) \rightarrow L^2(E_*; L^2(\mathbb{T})).

- Its inverse is given by:

\[ (\mathcal{V}_\Gamma^{-1} \psi)(x) = |E_*|^{-1/2} \int_{E_*} e^{i<\theta, x>} \psi(\theta, x) \, d\theta. \]
The Bloch-Floquet theory.

- \( \hat{H}^0 := \nu_{\Gamma} H^0 \nu_{\Gamma}^{-1} = \int_{E_*} \hat{H}^0(\theta) d\theta \)
  with \( \hat{H}^0(\theta) := (-i\nabla - \theta)^2 + V \) in \( L^2(\mathbb{T}) \).

- The map \( E_* \ni \theta \mapsto \hat{H}^0(\theta) \) has an extension to \( \mathcal{X}^* \) that is analytic in the norm resolvent topology and is given by
  \[
  \hat{H}^0(\theta + \gamma^*) = e^{i\langle \gamma^*, \cdot \rangle} \hat{H}^0(\theta) e^{-i\langle \gamma^*, \cdot \rangle}.
  \]

- There exists a family of continuous functions \( E_* \ni \theta \mapsto \lambda_j(\theta) \in \mathbb{R} \) with periodic continuous extensions to \( \mathcal{X}^* \supset E_* \), indexed by \( j \in \mathbb{N} \) such that \( \lambda_j(\theta) \leq \lambda_{j+1}(\theta) \) for every \( j \in \mathbb{N} \) and \( \theta \in E_* \), and
  \[
  \sigma(\hat{H}^0(\theta)) = \bigcup_{j \in \mathbb{N}} \{ \lambda_j(\theta) \}.
  \]

- There exists an orthonormal family of measurable eigenfunctions \( E_* \ni \theta \mapsto \hat{\phi}_j(\theta, \cdot) \in L^2(\mathbb{T}) \), \( j \in \mathbb{N} \), such that \( \| \hat{\phi}_j(\theta, \cdot) \|_{L^2(\mathbb{T})} = 1 \) and
  \[
  \hat{H}^0(\theta) \hat{\phi}_j(\theta, \cdot) = \lambda_j(\theta) \hat{\phi}_j(\theta, \cdot).
  \]
The Problem

The first Bloch band.

The first Bloch eigenvalue $\lambda_0(\theta)$ is always simple in a neighborhood of $\theta = 0$ and has a nondegenerate global minimum on $E_*$ at $\theta = 0$.

- Up to a shift in energy we may take this minimum to be equal to zero.
- Because $H^0$ has a real symbol, we have $\hat{H}^0(\theta) = \hat{H}^0(-\theta)$.
- Since $\lambda_0(\cdot)$ is simple, it must be an even function $\lambda_0(\theta) = \lambda_0(-\theta)$. 
The Problem

Non-crossing Hypothesis.

H.1: Non-crossing condition with a gap.

\[ \sup(\lambda_0) < \inf(\lambda_1). \]

or

H.2: Non-crossing condition with range overlapping and no gap.

The eigenvalue \( \lambda_0(\theta) \) remains simple for all \( \theta \in \mathbb{T}_* \), but \( \sup(\lambda_0) \geq \inf(\lambda_1) \).
The magnetic field.

We consider a 2-parameter family of magnetic fields

\[ B_{\epsilon,\kappa}(x) := \epsilon B_0 + \kappa \epsilon B(\epsilon x), \]

indexed by \((\epsilon, \kappa) \in [0, 1] \times [0, 1]\).

- \(B_0 > 0\) is constant.
- \(B : \mathcal{X} \to \mathbb{R}\) is smooth and bounded together with all its derivatives.

We choose some smooth vector potentials \(A^0 : \mathcal{X} \to \mathcal{X}\) and \(A : \mathcal{X} \to \mathcal{X}\) such that:

\[ B_0 = \partial_1 A_2^0 - \partial_2 A_1^0, \quad B = \partial_1 A_2 - \partial_2 A_1, \]

\[ A^{\epsilon,\kappa}(x) := \epsilon A^0(x) + \kappa A(\epsilon x), \quad B_{\epsilon,\kappa} = \partial_1 A_2^{\epsilon,\kappa} - \partial_2 A_1^{\epsilon,\kappa}. \]

The vector potential \(A^0\) is always in the transverse gauge, i.e.

\[ A^0(x) = (B_0/2)(-x_2, x_1). \]
The magnetic periodic Hamiltonian.

We consider the following magnetic Schrödinger operator:

\[ H^{\epsilon,\kappa} := (-i\partial_{x_1} - A_1^{\epsilon,\kappa})^2 + (-i\partial_{x_2} - A_2^{\epsilon,\kappa})^2 + V, \]

essentially self-adjoint on \( \mathcal{S}(\mathcal{X}) \).

When \( \kappa = \epsilon = 0 \) we recover the periodic Schrödinger Hamiltonian without magnetic field \( H^0 \).
The main result, for $B_{\varepsilon, \kappa}(x) = \varepsilon B_0 + \kappa \varepsilon B(\varepsilon x)$.

**Theorem**

Consider either Hypothesis H.1 or Hypothesis H.2. Fix an integer $N > 1$. Then there exist some constants $C_0, C_1, C_2 > 0$, and $\varepsilon_0, \kappa_0 \in (0, 1)$, such that for any $\kappa \in (0, \kappa_0]$ and $\varepsilon \in (0, \varepsilon_0]$ there exist $a_0 < b_0 < a_1 < \cdots < a_N < b_N$ with $a_0 = \inf \{\sigma(H^{\varepsilon, \kappa})\}$ so that:

- $\sigma(H^{\varepsilon, \kappa}) \cap [a_0, b_N] \subset \bigcup_{k=0}^{N} [a_k, b_k]$, \quad $\dim(\text{Ran} E_{[a_k, b_k]}(H^{\varepsilon, \kappa})) = +\infty$,
- $b_k - a_k \leq C_0 \kappa \varepsilon + C_1 \varepsilon^{4/3}$, $0 \leq k \leq N$,
- $a_{k+1} - b_k \geq C_2^{-1} \varepsilon$, $0 \leq k \leq N - 1$.

Moreover, given any compact set $K \subset \mathbb{R}$, there exists $C > 0$, such that, for $(\kappa, \varepsilon) \in [0, 1] \times [0, 1]$, we have (here $\text{dist}_H$ means Hausdorff distance):

$$\text{dist}_H(\sigma(H^{\varepsilon, \kappa}) \cap K, \sigma(H^{\varepsilon, 0}) \cap K) \leq C \sqrt{\kappa \varepsilon}.$$
The existing result, for $B_\epsilon(x) = \epsilon B_0$.

**Theorem (B. Helffer, J. Sjöstrand, LNP 345 (1989).)**

Suppose fixed some $E > 0$ small enough. Under Hypothesis H.1, for any $L \in \mathbb{N}^*$, there exist $\epsilon_0 > 0$ and $C > 0$, such that for $\epsilon \in (0, \epsilon_0]$ there exist $N(\epsilon)$ and $a_0 < b_0 < ... < a_N < b_N$ such that:

- $a_0 = \inf \{\sigma(H^{\epsilon,0})\}$,
- $\sigma(H^{\epsilon,0}) \cap (-\infty, E) \subset \bigcup_{k=0}^{N}[a_k, b_k]$,
- $|b_k - a_k| \leq C \epsilon^L$ for $0 \leq k \leq N(\epsilon)$,
- $a_{k+1} - b_k \geq \epsilon/C$ for $0 \leq k \leq N(\epsilon) - 1$.

$a_k$ is determined by a Bohr-Sommerfeld rule $a_k = f((2k + 1)\epsilon, \epsilon)$, where $t \mapsto f(t, \epsilon)$ has a complete expansion in powers of $\epsilon$, $f(0, 0) = \inf \lambda_0$ and $\partial_t f(0, 0) \neq 0$.
Main Steps of the Proof of the Main Result
Step 1: Construction of an effective magnetic matrix. (A)

1. \(\lambda_0(\theta)\) being assumed to be isolated, one can associate with it an orthonormal projection \(\pi_0\) commuting with \(H^0\). This might **not** be a spectral projection for \(H^0\), unless there is a gap between the first band and the rest (Hypothesis H.1).

2. Results by Nenciu, Cornean-Helffer-Nenciu and Fiorenza-Monaco-Panati show that in both cases the range of \(\pi_0\) has a basis consisting of exponentially localized Wannier functions.

3. When \(\epsilon\) and \(\kappa\) are small enough, we can construct an orthogonal system of exponentially localized *almost* Wannier functions starting from the unperturbed Wannier basis; the corresponding orthogonal projection \(\pi^{\epsilon,\kappa}_0\) is **almost invariant** for \(H^{\epsilon,\kappa}\). In the case with a gap (H.1), \(\pi^{\epsilon,\kappa}_0\) is a spectral projection for \(H^{\epsilon,\kappa}\).
Step 1: Construction of an effective magnetic matrix. (B)

1. Using a Feshbach-type argument, we prove that the low lying spectrum of $H^{\epsilon,\kappa}$ is at a Hausdorff distance of order $\epsilon^2$ from the spectrum of the reduced operator $\pi_0^{\epsilon,\kappa} \, H^{\epsilon,\kappa} \, \pi_0^{\epsilon,\kappa}$.

2. In the basis of magnetic almost Wannier functions, the reduced operator $\pi_0^{\epsilon,\kappa} \, H^{\epsilon,\kappa} \, \pi_0^{\epsilon,\kappa}$ defines an effective magnetic matrix acting on $\ell^2(\Gamma)$.

Conclusion 1.

If the effective magnetic matrix has spectral gaps of order $\epsilon$, the same holds true for the bottom of the spectrum of $H^{\epsilon,\kappa}$. 
Step 2: Replacing the magnetic matrix with a magnetic pseudodifferential operator with periodic symbol.

1. For $\kappa = 0$, i.e. for a constant magnetic field $\epsilon B_0$, we define a periodic magnetic Bloch band function $\lambda^\epsilon$ which is a perturbation of order $\epsilon$ of the first Bloch eigenvalue $\lambda_0$.

2. Considering this magnetic Bloch band function as a periodic symbol, we may define its magnetic quantization $\mathcal{O}p^{A^\epsilon, \kappa}(\lambda^\epsilon)$ in the magnetic field $B^\epsilon, \kappa$.

3. It turns out that the spectrum of $\mathcal{O}p^{A^\epsilon, \kappa}(\lambda^\epsilon)$ is located at a Hausdorff distance of order $\kappa \epsilon$ from the spectrum of the effective operator $\pi_0^{\epsilon, \kappa} H^\epsilon, \kappa \pi_0^{\epsilon, \kappa}$.

Conclusion 2.

Hence if $\mathcal{O}p^{A^\epsilon, \kappa}(\lambda^\epsilon)$ has gaps of order $\epsilon$ (provided that $\kappa$ is smaller than some constant independent of $\epsilon$), the same is true for the bottom of the spectrum of $H^\epsilon, \kappa$. 

Radu Purice (IMAR)
Step 3: Spectral analysis of $\mathcal{D}p^{A^\epsilon,\kappa}(\lambda^\epsilon)$.

1. We compare the spectrum of $\mathcal{D}p^{A^\epsilon,\kappa}(\lambda^\epsilon)$ with the spectrum of a Landau-type quadratic symbol defined using the Hessian of $\lambda^\epsilon$ near its simple, isolated minimum; this is achieved by proving that the magnetic quantization of an explicitly defined symbol is in fact a quasi-resolvent for the magnetic quantization of $\lambda^\epsilon$.

2. An important technical component is the development of a magnetic Moyal calculus for symbols with weak spatial variation that replaces the Moyal calculus for a constant field as appearing in the previous papers by Helffer and his coworkers.
The magnetic pseudodifferential calculus with slowly variable symbols
Let us denote by $\mathcal{X}^*$ the dual of $\mathcal{X}$ (the momentum space) with $\langle \cdot, \cdot \rangle : \mathcal{X}^* \times \mathcal{X} \to \mathbb{R}$ denoting the duality map.

Let $\Xi := \mathcal{X} \times \mathcal{X}^*$ be the phase space with the canonical symplectic form

$$\sigma(X, Y) := \langle \xi, y \rangle - \langle \eta, x \rangle,$$

for $X := (x, \xi) \in \Xi$ and $Y := (y, \eta) \in \Xi^*$.

We consider the spaces $BC(V)$ of bounded continuous functions on any finite dimensional real vector space $V$ with the $\| \cdot \|_\infty$ norm.

We shall denote by $C^\infty(V)$ the space of smooth functions on $V$ and by $C^\infty_{pol}(V)$ (resp. by $BC^\infty(V)$) its subspace of smooth functions that are polynomially bounded together with all their derivatives, (resp. smooth and bounded together with all their derivatives), endowed with the usual locally convex topologies.
The magnetic pseudodifferential calculus

Given a vector potential $A$ with components of class $C^\infty_{\text{pol}}(\mathcal{X})$, for any tempered distribution $F \in \mathcal{S}'(\Xi)$ we can associate the following linear operator (defined as oscillatory integral):

$$\mathcal{S}(\mathcal{X}) \ni u \mapsto (\mathcal{O}p^A(F)u)(x) := (2\pi)^{-2} \int_{\mathcal{X}} \int_{\mathcal{X}^*} e^{i\langle \xi, x-y \rangle} e^{-i \int_{[x,y]} A} F \left( \frac{x+y}{2}, \xi \right) u(y) \, d\xi \, dy.$$  

**Remark**

The application $\mathcal{O}p^A$ extends to a linear and topological isomorphism between $\mathcal{S}'(\Xi)$ and $\mathcal{L}(\mathcal{S}(\mathcal{X}); \mathcal{S}'(\mathcal{X}))$ (considered with the strong topologies).
The magnetic pseudodifferential calculus

The operator composition of the operators $\mathcal{Op}^A(F)$ and $\mathcal{Op}^A(G)$ induces a *twisted Moyal product*, also called magnetic Moyal product, such that

$$\mathcal{Op}^A(F) \mathcal{Op}^A(G) = \mathcal{Op}^A(F \#^B G).$$

This product depends only on the magnetic field $B$ and is given by the following oscillating integrals:

$$(F \#^B G)(X) := \pi^{-4} \int_{\Xi} dY \int_{\Xi} dZ \ e^{-2i\sigma(Y,Z)} e^{-i \int_{T(x,y,z)}^B F(X - Y) G(X - Z)}$$

$$= \pi^{-4} \int_{\Xi} dY \int_{\Xi} dZ \ e^{-2i\sigma(X - Y, X - Z)} e^{-i \int_{\tilde{T}(x,y,z)}^B F(Y) G(Z)},$$

where $T(x,y,z)$ is the triangle of vertices $x - y - z$, $x + y - z$, $x - y + z$ and $\tilde{T}(x,y,z)$ the triangle in $\mathcal{X}$ of vertices $x - y + z$, $y - z + x$, $z - x + y$. 
The magnetic pseudodifferential calculus

Hörmander type symbols

For any $s \in \mathbb{R}$ and any $\rho \in [0, 1]$, we denote by

$$S^s_\rho(\Xi) := \{ F \in C^\infty(\Xi) \mid \nu_{n,m}^{s,\rho}(F) < +\infty, \forall (n, m) \in \mathbb{N} \times \mathbb{N} \},$$

where

$$\nu_{n,m}^{s,\rho}(f) := \sup_{(x,\xi) \in \Xi} \sum_{|\alpha| \leq n} \sum_{|\beta| \leq m} |\langle \xi \rangle^{-s+\rho m} (\partial^\alpha_x \partial^\beta_\xi f)(x, \xi)|.$$

$$S^\infty_\rho(\Xi) := \bigcup_{s \in \mathbb{R}} S^s_\rho(\Xi) \text{ and } S^{-\infty}_\rho(\Xi) := \bigcap_{s \in \mathbb{R}} S^s_\rho(\Xi).$$

Remark

For symbols of class $S^0_0(\Xi)$ the associated magnetic pseudodifferential operator is bounded in $\mathcal{H}$. 

Radu Purice (IMAR)
The magnetic pseudodifferential calculus

For any symbol $F$ we denote by $F_{B}^{-}$ its inverse with respect to the magnetic Moyal product, if it exists.

Proposition

1. For any $m > 0$ and for $a > 0$ large enough (depending on $m$) the symbol $s_{m}(x, \xi) := \langle \xi \rangle^{m} + a$, has an inverse for the magnetic Moyal product.

2. If $F \in S_{\rho}^{0}(\Xi)$ is invertible for the magnetic Moyal product, then the inverse $F_{B}^{-}$ also belongs to $S_{\rho}^{0}(\Xi)$.

3. For $m < 0$, if $f \in S_{\rho}^{m}(\Xi)$ is such that $1 + f$ is invertible for the magnetic Moyal product, then $(1 + f)_{B}^{-} - 1 \in S_{\rho}^{m}(\Xi)$.

4. Let $m > 0$ and $\rho \in [0, 1]$. If $G \in S_{\rho}^{m}(\Xi)$ is invertible for the magnetic Moyal product, with $Op^{A}(s_{m} \# B G_{B}^{-}) \in L(L^{2}(\mathcal{X}))$, then $G_{B}^{-} \in S_{\rho}^{-m}(\Xi)$. 
The magnetic pseudodifferential calculus

Definition

A symbol $F$ in $S^s_p(\Xi)$ is called elliptic if there exist two positive constants $R$ and $C$ such that

$$|F(x, \xi)| \geq C \langle \xi \rangle^s,$$

for any $(x, \xi) \in \Xi$ with $|\xi| \geq R$.

Remark

For any real elliptic symbol $h \in S^m_1(\Xi)_\Gamma$ (with $m > 0$) and for any $A$ in $C^\infty_{pol}(\mathcal{X}, \mathbb{R}^2)$, the operator $\mathcal{Op}^A(h)$ has a closure $H^A$ in $L^2(\mathcal{X})$ that is self-adjoint on a domain $\mathcal{H}^m_A$ (a magnetic Sobolev space) and lower semibounded. Thus we can define its resolvent $(H^A - z)^{-1}$ for any $z \notin \sigma(H^A)$ and it exists a symbol $r^B_z(h) \in S_1^{-m}(\Xi)$ such that

$$(H^A - z)^{-1} = \mathcal{Op}^A(r^B_z(h)).$$
Weak magnetic fields

Let \( B_\epsilon := \epsilon B_0^0 \), with \( B_0^0 \in BC^\infty(\mathcal{X}) \) uniformly for \( \epsilon \in [0, \epsilon_0] \). Let \( H^\epsilon \) be the self-adjoint extension of \( \mathcal{O}p^\epsilon(h) \) for an elliptic real symbol \( h \in S_1^m(\Xi) \) with \( m > 0 \). For \( z \in \rho(H^\epsilon) \), let \( r_z^\epsilon(h) \in S_1^{-m}(\Xi) \) denote the symbol of \((H^\epsilon - z)^{-1}\).

**Proposition**

For any compact subset \( K \) of \( \mathbb{C} \setminus \sigma(H) \), there exists \( \epsilon_0 > 0 \) such that:

1. \( K \subset \mathbb{C} \setminus \sigma(H^\epsilon) \), for \( \epsilon \in [0, \epsilon_0] \).

2. The following expansion is convergent in \( \mathcal{L}(\mathcal{H}) \) uniformly with respect to \( (\epsilon, z) \in [0, \epsilon_0] \times K \):

\[
    r_z^\epsilon(h) = \sum_{n \in \mathbb{N}} \epsilon^n r_n(h; \epsilon, z), \quad r_0(h; \epsilon, z) = r_z^0(h), \quad r_n(h; \epsilon, z) \in S_1^{-(m+2n)}(\Xi).
\]

3. The map \( K \ni z \mapsto r_z^\epsilon(h) \in S_1^{-m}(\Xi) \) is a \( S_1^{-m}(\Xi) \)-valued analytic function, uniformly in \( \epsilon \in [0, \epsilon_0] \).
Slowly varying symbols

Definition

For any \((m, \rho) \in \mathbb{R} \times [0, 1]\) and for some \(\epsilon_0 > 0\), we denote by \(S^m_\rho(\Xi)^\bullet\) the families of symbols \(\{F^\epsilon\}_{\epsilon \in [0, \epsilon_0]}\) satisfying the following properties:

1. \(F^\epsilon \in S^m_\rho(\Xi), \forall \epsilon \in [0, \epsilon_0];\)
2. \(\exists \lim_{\epsilon \searrow 0} F^\epsilon := F^0 \in S^m_\rho(\Xi)\) in the topology of \(S^m_\rho(\Xi);\)
3. \(\forall (\alpha, \beta) \in \mathbb{N}^2 \times \mathbb{N}^2, \exists C_{\alpha\beta} > 0\) such that
   \[
   \sup_{\epsilon \in (0, \epsilon_0]} \epsilon^{-|\alpha|} \left\| \partial_x^\alpha \partial_\xi^\beta F^\epsilon \right\|_\infty \leq C_{\alpha\beta}.
   \]

The following seminorms indexed by \((p, q) \in \mathbb{N}^2\)

\[
F^\bullet \mapsto \tilde{\nu}^{m, \rho}_{p, q}(F^\bullet) := \sup_{\epsilon \in [0, \epsilon_0]} \epsilon^{-p} \sum_{|\alpha| = p} \sum_{|\beta| = q} \sup_{(x, \xi) \in \Xi} < \xi >^{-(m-q\rho)} \left| \left( \partial_x^\alpha \partial_\xi^\beta F^\epsilon \right)(x, \xi) \right|
\]

define the topology on \(S^m_\rho(\Xi)^\bullet\).
Remark

Defining $\tilde{F}^\epsilon(x, \xi) := F^\epsilon(\epsilon^{-1}x, \xi)$, it is easy to see that

$\{F^\epsilon\}_{\epsilon \in [0, \epsilon_0]} \subset S^m_\rho(\Xi)$ belongs to $S^m_\rho(\Xi)^*$ if and only if it is of the form

$F^\epsilon(x, \xi) = \tilde{F}^\epsilon(\epsilon x, \xi) = \tilde{F}^\epsilon(\epsilon, 1)(x, \xi)$ for some bounded family

$\{\tilde{F}^\epsilon\}_{\epsilon \in [0, \epsilon_0]} \subset S^m_\rho(\Xi)$ verifying the condition

$$\exists \lim_{\epsilon \searrow 0} \tilde{F}^\epsilon(0, \cdot) := F^0 \in S^m_\rho(\Xi) \bigcap C^\infty_{\text{pol}}(\mathcal{X}^*)$$
Suppose $B_{\epsilon,\kappa}(x) = \epsilon B_0 + \kappa \epsilon B(\epsilon x)$.

**Proposition**

If $f^\bullet \in S^m_\rho(\Xi)^\bullet$ and $g^\bullet \in S^p_\rho(\Xi)^\bullet$, then $\{f^{\epsilon \#} B_{\epsilon,\kappa} g^{\epsilon}\}_{\epsilon \in [0,\epsilon_0]}$ belongs to $S^{m+p}_\rho(\Xi)^\bullet$ uniformly with respect to $\kappa \in [0,1]$.

**Proposition**

If $f^\bullet \in S^m_\rho(\Xi)^\bullet$ and if the inverse $(f^{\epsilon})^- \equiv (f^{\epsilon})_{B_{\epsilon,\kappa}}^- \in S^{-m}_\rho(\Xi)$ exists for every $\epsilon \in [0,\epsilon_0]$, then $\{(f^{\epsilon})^-\}_{\epsilon \in [0,\epsilon_0]} \in S^{-m}_\rho(\Xi)^\bullet$. 
Magnetic almost-Wannier Functions
The Wannier functions.

Under any Hypothesis H.1 or H.2,
- the analyticity in norm of the application $\mathcal{X}^* \ni \theta \to \hat{H}^0(\theta)$,
- the contour integral formula for the spectral projection,

allow one to define a $L^2$-normalized eigenfunction for the eigenvalue $\lambda_0$ as an analytic function $\mathcal{X}^* \ni \theta \to \hat{\phi}_0(\theta, \cdot) \in L^2(\mathbb{T})$ such that

$$
\hat{\phi}_0(\theta + \gamma^*, x) = e^{i\langle \gamma^*, x \rangle} \hat{\phi}_0(\theta, x),
$$

$$
\hat{H}^0(\theta) \hat{\phi}_0(\theta, \cdot) = \lambda_0(\theta) \hat{\phi}_0(\theta, \cdot).
$$

Then the principal Wannier function $\phi_0$ is defined by:

$$
\phi_0(x) = \left[ \mathcal{V}_\Gamma^{-1} \hat{\phi}_0 \right](x) = |E_*|^{-\frac{1}{2}} \int_{E_*} e^{i\langle \theta, x \rangle} \hat{\phi}_0(\theta, x) d\theta.
$$
The Wannier functions.

$\phi_0$ has rapid decay

$\exists C > 0$ such that $\forall \alpha \in \mathbb{N}^2$, $\exists C_\alpha > 0$ such that

$$|\partial_\alpha^x \phi_0(x)| \leq C_\alpha \exp\left(-|x|/C\right), \forall x \in \mathbb{R}^2.$$

We shall also consider the associated orthogonal projections

$$\hat{\pi}_0(\theta) := |\hat{\phi}_0(\theta, \cdot) \rangle \langle \hat{\phi}_0(\theta, \cdot)|, \quad \pi_0 := \mathcal{V}_\Gamma^{-1}\left(\int_{E_x}^\oplus \hat{\pi}_0(\theta)d\theta\right)\mathcal{V}_\Gamma.$$

Remark

The family $\{\phi_\gamma := \tau_{-\gamma} \phi_0\}_{\gamma \in \Gamma}$ is an orthonormal basis for $\pi_0 \mathcal{H}$.

Remark

Under Hypothesis H.1, $\pi_0$ is the spectral projection associated to $\lambda_0$. 

Radu Purice (IMAR)  Spectral gaps  Santiago de Chile  32 / 51
Let us consider first the constant magnetic field $B_\epsilon := \epsilon B_0$.

**Definition**

1. For any $\gamma \in \Gamma$ and with $A^0$ defined above we define:
   \[
   \phi^\circ_{\gamma}(x) := \Lambda^\epsilon(x, \gamma)\phi_0(x - \gamma), \quad \Lambda^\epsilon(x, y) := \exp\left\{-i\epsilon \int_{[x,y]} A^0\right\}.
   \]

2. $\pi_0^\epsilon$: the orthogonal projection on the closed linear span of $\{\phi^\circ_{\gamma}\}_{\gamma \in \Gamma}$.

3. $G^\epsilon_{\alpha\beta} := \langle \phi^\circ_{\alpha}, \phi^\circ_{\beta}\rangle_\mathcal{H}$: the infinite *Gramian matrix*, indexed by $\Gamma \times \Gamma$.

4. $F^\epsilon := (G^\epsilon)^{-1/2}$. 
The magnetic almost-Wannier functions.

**Proposition**

The matrix $G^\epsilon$ defines a positive bounded operator on $\ell^2(\Gamma)$.

$F^\epsilon$ has the following properties:

1. $F^\epsilon \in \mathcal{L}(\ell^2(\Gamma)) \cap \mathcal{L}(\ell^\infty(\Gamma))$.

2. For any $m \in \mathbb{N}$, there exists $C_m > 0$ such that

$$\sup_{(\alpha, \beta) \in \Gamma \times \Gamma} \langle \alpha - \beta \rangle^m |F^\epsilon_{\alpha\beta} - 1| \leq C_m \epsilon, \forall \epsilon \in [0, \epsilon_0].$$

3. There exists a rapidly decaying function $F^\epsilon : \Gamma \to \mathbb{C}$ such that for any pair $(\alpha, \beta) \in \Gamma \times \Gamma$ we have:

$$F^\epsilon_{\alpha,\beta} = \Lambda^\epsilon(\beta, \alpha) F^\epsilon(\beta - \alpha).$$
The magnetic almost-Wannier functions.

For all $\epsilon \in [0, \epsilon_0]$ we can define the following orthonormal basis of $\tilde{\pi}_0^\epsilon \mathcal{H}$:

$$\phi^\epsilon_\gamma := \sum_{\alpha \in \Gamma} F^\epsilon_{\alpha\gamma} \phi^0_\alpha, \forall \gamma \in \Gamma.$$ 

Proposition

With $\psi^\epsilon_0$ in $\mathcal{S}(\mathbb{R}^2)$ defined by

$$\psi^\epsilon_0(x) = \sum_{\alpha \in \Gamma} F^\epsilon(\alpha) \Lambda^\epsilon(\alpha, x) \phi_0(x - \alpha),$$

we have

$$\phi^\epsilon_\gamma = \Lambda^\epsilon(\cdot, \gamma)(\tau_{-\gamma} \psi^\epsilon_0), \quad \forall \gamma \in \Gamma.$$
The magnetic almost-Wannier functions.

Consider now \( B_{\epsilon, \kappa} := \epsilon B_0 + \kappa \epsilon B(\epsilon x) \) let us choose some smooth vector potential \( A(y) \) such that \( dA = B \) and introduce

\[
A_\epsilon(x) := A(\epsilon x) \quad \text{and} \quad \tilde{\Lambda}^{\epsilon, \kappa}(x, y) := \exp \left\{ -i \kappa \int_{[x,y]} A_\epsilon \right\},
\]

Definition

- \( \phi^{\epsilon, \kappa}_\gamma = \tilde{\Lambda}^{\epsilon, \kappa}(\cdot, \gamma) \phi^{\epsilon}_\gamma \).
- \( \tilde{\pi}_{0}^{\epsilon, \kappa} \) as the orthogonal projection on the closed linear span of \( \{ \phi^{\epsilon, \kappa}_\gamma \}_{\gamma \in \Gamma} \).
- \( \{ \tilde{\phi}^{\epsilon, \kappa}_\gamma \}_{\gamma \in \Gamma} \) the orthonormal basis of \( \tilde{\pi}_{0}^{\epsilon, \kappa} \) obtained from \( \{ \phi^{\epsilon, \kappa}_\gamma \}_{\gamma \in \Gamma} \) by the Gramm-Schmidt procedure.
The magnetic almost-Wannier functions.

The explicit form of the symbols of the projections $\tilde{\pi}^{\epsilon,\kappa}_0$ and $\pi_0$ allow us to use the magnetic pseudodifferential calculus with slowly varying symbols in order to prove that:

**Proposition**

There exist $\epsilon_0 > 0$ and $C > 0$ such that, for any $(\epsilon, \kappa) \in [0, \epsilon_0] \times [0, 1]$, the range of $\tilde{\pi}^{\epsilon,\kappa}_0$ belongs to the domain of $H^{\epsilon,\kappa}$ and

$$\left\| \left[ H^{\epsilon,\kappa}, \tilde{\pi}^{\epsilon,\kappa}_0 \right] \right\|_{L(H)} \leq C \epsilon .$$

**Definition**

We call *quasi-band magnetic Hamiltonian*, the operator $\tilde{\pi}^{\epsilon,\kappa}_0 H^{\epsilon,\kappa} \tilde{\pi}^{\epsilon,\kappa}_0$ and *quasi-band magnetic matrix*, its form in the orthonormal basis $\{ \tilde{\phi}^{\epsilon,\kappa}_\gamma \}_{\gamma \in \Gamma}$.
The magnetic quasi Bloch function.

Definition

We define $h^\epsilon \in \ell^2(\Gamma)$ by:

$$h^\epsilon(\gamma) := \langle \psi^\epsilon_0, \Lambda^\epsilon(x, \gamma) \tau_{-\gamma} H^\epsilon \psi^\epsilon_0 \rangle_{\mathcal{H}} = \langle \phi^\epsilon_0, H^\epsilon \phi^\epsilon_{-\gamma} \rangle_{\mathcal{H}} \quad \text{for } \gamma \in \Gamma,$$

and the magnetic quasi Bloch function $\lambda^\epsilon$ as its discrete Fourier transform:

$$\lambda^\epsilon : \mathbb{T}_* \to \mathbb{R}, \quad \lambda^\epsilon(\theta) := \sum_{\gamma \in \Gamma} h^\epsilon(\gamma) e^{-i<\theta,\gamma>}.$$

Proposition

There exists $\epsilon_0 > 0$ such that, for $\epsilon \in [0, \epsilon_0]$ and $\kappa \in [0, 1]$, the Hausdorff distance between the spectra of the magnetic quasi-band Hamiltonian $\tilde{\pi}_0^\epsilon, \kappa H^\epsilon, \kappa \tilde{\pi}_0^\epsilon, \kappa$ and $\mathcal{D} \phi^\epsilon, \kappa(\lambda^\epsilon)$ is of order $\kappa \epsilon$. 
The Feshbach type argument
The Feshbach type argument

In order to apply a Feshbach type argument we need to control the invertibility on the orthogonal complement of $\tilde{\pi}_0^\epsilon,\kappa H$.

Let us define

1. $\tilde{\pi}_\perp^\epsilon,\kappa := 1 - \tilde{\pi}_0^\epsilon,\kappa$.

2. $m_1 := \inf_{\theta \in \mathbb{T}^*} \lambda_1(\theta)$ where $\lambda_1$ is the second Bloch eigenvalue.

3. $K^\epsilon,\kappa := H^\epsilon,\kappa + m_1 \tilde{\pi}_0^\epsilon,\kappa$.

**Proposition**

There exist $\epsilon_0$ and $C > 0$ such that, for $\epsilon \in [0, \epsilon_0]$, $K^\epsilon,\kappa \geq m_1 - C\epsilon > 0$.

**Proposition**

There exists $\epsilon_0 > 0$ such that for $\epsilon \in [0, \epsilon_0]$, the Hausdorff distance between the spectra of $H^\epsilon,\kappa$ and $\tilde{\pi}_0^\epsilon,\kappa H^\epsilon,\kappa \tilde{\pi}_0^\epsilon,\kappa$, both restricted to the interval $[0, \frac{m_1}{2}]$, is of order $\epsilon^2$. 
The magnetic quantization of the magnetic quasi Bloch function
Properties of the magnetic quasi Bloch function

Proposition

For the magnetic quasi Bloch function $\lambda^\epsilon$ defined above there exists $\epsilon_0 > 0$ such that $\lambda^\epsilon(\theta) = \lambda_0(\theta) + \epsilon \rho^\epsilon(\theta)$, with $\rho^\epsilon \in BC^\infty(\mathbb{T}_*)$ uniformly in $\epsilon \in [0, \epsilon_0]$ and such that $\rho^\epsilon - \rho^0 = \mathcal{O}(\epsilon)$.

- Considering the function $\lambda^\epsilon$ as a $\Gamma_*$-periodic function on $\mathcal{X}^*$, a consequence of this Proposition is that the modified Bloch eigenvalue $\lambda^\epsilon \in C^\infty(\mathcal{X}^*)$ will also have an isolated non-degenerate minimum at some point $\theta^\epsilon \in \mathcal{X}^*$ close to $0 \in \mathcal{X}^*$.
- Using the evenness of $\lambda_0$ we get that in a neighborhood of $0 \in \mathbb{T}_*$ we have the expansions

$$
\lambda_0(\theta) = \sum_{1 \leq j, k \leq 2} a_{jk} \theta_j \theta_k + \mathcal{O}(|\theta|^4), \quad a_{jk} := \left( \partial_{jk}^2 \lambda_0 \right)(0);
$$

$$
\lambda^\epsilon(\theta) - \lambda^\epsilon(\theta^\epsilon) = \sum_{1 \leq j, k \leq 2} a^\epsilon_{jk} (\theta_j - \theta^\epsilon_j)(\theta_k - \theta^\epsilon_k) + \epsilon \mathcal{O}(|\theta - \theta^\epsilon|^3) + \mathcal{O}(|\theta - \theta^\epsilon|^4).
$$
The magnetic quantization of the magnetic quasi Bloch function

The Hessian at the minimum of the magnetic quasi Bloch function

There exists \( \epsilon_0 > 0 \) such that, for \( \epsilon \in [0, \epsilon_0] \), we can choose a local coordinate system on a neighborhood of \( \theta^\epsilon \in \mathcal{X}^* \) that diagonalizes the symmetric positive definite matrix \( a^\epsilon \) and we denote by 
\[
0 < m_1^\epsilon \leq m_2^\epsilon
\]
its eigenvalues.

We denote by 
\[
0 < m_1 \leq m_2
\]
the two eigenvalues of the matrix \( a_{jk} \).

We notice that
\[
m_j^\epsilon = m_j + \epsilon \mu_j + \mathcal{O}(\epsilon^2) \text{ for } j = 1, 2,
\]
with \( \mu_j \) explicitly computable.

Our goal is to obtain spectral information concerning the Hamiltonian
\[
\mathcal{D} p^{\epsilon, \kappa}(\lambda^\epsilon)
\]
starting from the spectral information about \( \mathcal{D} p^{\epsilon, \kappa}(h_{m^\epsilon}) \) with
\[
h_{m^\epsilon}(\xi) := m_1^\epsilon \xi_1^2 + m_2^\epsilon \xi_2^2,
\]
defining an elliptic symbol of class \( S^2_1(\Xi) \) that does not depend on the configuration space variables.
The model Landau Hamiltonian

We compare the bottom of the spectra of the following two operators

- the magnetic Hamiltonians $\mathcal{D}p^{\epsilon,\kappa}(h_m^\epsilon)$,
- the constant field magnetic Landau operator $\mathcal{D}p^{\epsilon,0}(h_m^\epsilon)$.

Proposition

For any compact set $M$ in $\mathbb{R}$, there exist $\epsilon_K > 0$, $C > 0$ and $\kappa_K \in (0, 1]$, such that for any $(\epsilon, \kappa) \in [0, \epsilon_K] \times [0, \kappa_K]$, the spectrum of the operator $\mathcal{D}p^{\epsilon,\kappa}(h_m^\epsilon)$ in $\epsilon M$ is contained in bands of width $C\kappa\epsilon$ centered at $\{(2n + 1)\epsilon m^\epsilon B_0\}_{n \in \mathbb{N}}$. 
The resolvent of $\mathcal{D}p^{\varepsilon,\kappa}(\lambda^\varepsilon)$
Isolating the minimum

- We choose an even function $\chi$ in $C_0^\infty(\mathbb{R})$ with $0 \leq \chi \leq 1$, with $\text{supp } \chi \subset (-2, +2)$ and $\chi(t) = 1$ on $[-1, +1]$.
- For $\delta > 0$ we define $g_{1/\delta}(\xi) := \chi(h_{m^\epsilon}(\delta^{-1}\xi))$, $\xi \in \mathcal{X}^*$.
- We choose $\delta^0$ such that $D(0, \sqrt{2m_1^{-1}\delta^0}) \subset \overset{\circ}{E}_*$ where $D(0, \rho)$ denotes the disk centered at 0 of radius $\rho$ and $\overset{\circ}{E}_*$ denotes the interior of $E_*$.
- For any $\delta \in (0, \delta_0]$ we associate $\delta^0 := \sqrt{m_1/2m_2} \delta$ so that we have $g_{1/\delta^0} = g_{1/\delta} g_{1/\delta^0}$.

For any $\delta \in (0, \delta_0]$, $g_{1/\delta} \in C_0^\infty(E_*)$.
- We may consider it as an element of $C_0^\infty(\mathcal{X}^*)$ by extending it by 0.
- We may define its $\Gamma_*$-periodic continuation to $\mathcal{X}^*$:

$$\tilde{g}_{1/\delta}(\xi) := \sum_{\gamma \in \Gamma_*} g_{1/\delta}(\xi - \gamma),$$
The $\epsilon$-dependent cut-off

**Hypothesis**

We shall impose the following scaling of the cut-off parameter $\delta > 0$:

$$\epsilon = \delta^\mu, \text{ for some } \mu \in (2, 4).$$

Then we have the following estimation near the minimum:

$$\lambda^\epsilon(\xi)g_{1/\delta}(\xi) = g_{1/\delta}(\xi) h_{m^\epsilon}(\xi) + \mathcal{O}(\delta^4), \quad \text{with } \delta^4 \ll \epsilon.$$
The \textit{shift} outside the minimum

For the region outside the minima, we need the operator:

\[ \mathcal{D} p^{\epsilon, \kappa}(\lambda^\epsilon + (\delta^\circ)^2 \tilde{g}_1/\delta^\circ). \]

**Proposition**

There exists \( \epsilon_0 > 0 \) and for \((\epsilon, \kappa, \delta) \in [0, \epsilon_0] \times [0, 1] \times (0, \delta_0]\), there exists some constant \( C'(\epsilon, \delta) > 0 \) such that:

\[ \mathcal{D} p^{\epsilon, \kappa}(\lambda^\epsilon + (\delta^\circ)^2 \tilde{g}_1/\delta^\circ) \geq (C' \delta^2 - C'(\epsilon, \delta) \epsilon) \mathbb{1}. \]
The "quasi-inverse".

Let us fix $\mu = 3 \in (2, 4)$ and some compact set $K \subset \mathbb{C}$ such that:

$$K \subset \mathbb{C} \setminus \{(2n + 1)mB_0\}_{n \in \mathbb{N}}.$$ 

There exist $\epsilon_K > 0$ and $\kappa_K \in [0, 1]$ such that for $(\epsilon, \kappa) \in [0, \epsilon_K] \times [0, \kappa_K]$ and for $a \in K$, the point $\epsilon a \in \mathbb{C}$ belongs to the resolvent set of $\mathcal{D}p^{\epsilon, \kappa}(h_{m^\epsilon})$.

We denote by $r^{\epsilon, \kappa}(\epsilon a)$ the magnetic symbol of $(\mathcal{D}p^{\epsilon, \kappa}(h_{m^\epsilon}) - \epsilon a)^{-1}$.

The quasi-inverse

For $a \in K$ we want to define the following symbol in $\mathcal{L}^\prime(\mathcal{X}^*)$ as the sum of the series on the right hand side:

$$\tilde{r}_\lambda(\epsilon a) := \sum_{\gamma^* \in \Gamma^*} \tau_{\gamma^*} \left( g_{1/\delta} \#^{\epsilon, \kappa} r^{\epsilon, \kappa}(\epsilon a) \right) + \left( 1 - \tilde{g}_{1/\delta} \right) \#^{\epsilon, \kappa} r_{\delta, \epsilon, \kappa}(\epsilon a), \quad \delta = \epsilon^{1/\mu}.$$
The "quasi-inverse".

Proposition

For $\mu$ and $K$ as above, there exist $C > 0$, $\kappa_0 \in (0, 1]$ and $\epsilon_0 > 0$ such that for $(\kappa, \epsilon, a) \in [0, \kappa_0] \times (0, \epsilon_0] \times K$, the symbol $\tilde{r}_\lambda(\epsilon a)$ is well defined and we have

$$
\| \mathcal{D} p^{\epsilon, \kappa}(\tilde{r}_\lambda(\epsilon a)) \| \leq C \epsilon^{-1},
$$

and

$$(\lambda_\epsilon - \epsilon a) \#^{\epsilon, \kappa} \tilde{r}_\lambda(\epsilon a) = 1 + r_{\delta, a}, \text{ with } \| \mathcal{D} p^{\epsilon, \kappa}(r_{\delta, a}) \| \leq C \epsilon^{1/3}.$$  

For $N > 0$, there exist $C$, $\epsilon_0$ and $\kappa_0$ such that the spectrum of $\mathcal{D} p^{\epsilon, \kappa}(\lambda_\epsilon)$ in $[0, (2N + 2)mB_0 \epsilon]$ consists of spectral islands centered at $(2n + 1)mB_0 \epsilon$, $0 \leq n \leq N$, with a width bounded by $C (\epsilon \kappa + \epsilon^{4/3})$. 
Thank you for your attention.
