- CS and Richard Szabo, in preparation

Two-plectic Manifolds

Multisymplectic manifolds are a natural generalization of symplectic manifolds.

Symplectic manifolds

Manifold M with closed 2-form ω such that $\iota_v \omega = 0 \Leftrightarrow v = 0$.

- Poisson structure → Phase spaces in Hamiltonian dynamics.
- Starting point for quantization.

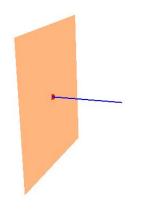

p-plectic manifolds

Manifold M with closed p+1-form ω such that $\iota_v\omega=0 \Leftrightarrow v=0$.

- 1-plectic: symplectic, 2-plectic: 3-form ω
- Often) Nambu-Poisson structure → multiphase spaces in Nambu mechanics.
- Might be starting point for higher quantization?
- Why should we be interested in such manifolds?
- Why should we quantize them?

D1-D3-Branes and the Nahm Equation

D1-branes ending on D3-branes can be described by the Nahm equation.

D1-branes ending on D3-branes:

A Monopole appears.

 $X^i \in \mathfrak{u}(N)$: transverse fluctuations

Nahm equation: $(s = x^6)$

$$\frac{\mathrm{d}}{\mathrm{d}s}X^i + \varepsilon^{ijk}[X^j, X^k] = 0$$

Note SO(3)-invariance.

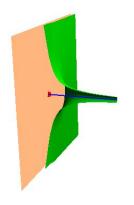

Solution: $X^i = r(s)G^i$ with

$$r(s) = \frac{1}{s}$$
, $G^i = \varepsilon^{ijk}[G^j, G^k]$

Nahm, Diaconescu, Tsimpis

D1-D3-Branes and the Nahm Equation

The D1-branes end on the D3-branes by forming a fuzzy funnel.

Solution:
$$X^i = r(s)G^i$$

$$r(s) = \frac{1}{s}$$
, $G^i = \varepsilon^{ijk}[G^j, G^k]$

Matches profile from SUGRA analysis

The D1-branes form a fuzzy funnel:

 G^i form irrep of $\mathfrak{su}(2)$: coordinates on fuzzy sphere S^2_F

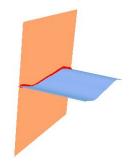

D1-worldvolume polarizes: $2d \rightarrow 4d$ Myers

Lifting D1-D3-Branes to M2-M5-Branes

The lift to M-theory is performed by a T-duality and an M-theory lift

The Basu-Harvey lift of the Nahm Equation

M2-branes ending on M5-branes yield a Nahm equation with a cubic term.

Basu, Harvey, hep-th/0412310

A Self-Dual String appears.

Substitute SO(3)-inv. Nahm eqn.

$$\frac{\mathrm{d}}{\mathrm{d}s}X^i + \varepsilon^{ijk}[X^j, X^k] = 0$$

by the SO(4)-invariant equation

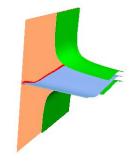

$$\frac{\mathrm{d}}{\mathrm{d}s}X^{\mu} + \varepsilon^{\mu\nu\rho\sigma}[X^{\nu}, X^{\rho}, X^{\sigma}] = 0$$

Solution: $X^{\mu} = r(s)G^{\mu}$ with

$$r(s) = \frac{1}{\sqrt{s}}, G^{\mu} = \varepsilon^{\mu\nu\rho\sigma}[G^{\nu}, G^{\rho}, G^{\sigma}]$$

The Basu-Harvey lift of the Nahm Equation

Also M2-branes end on M5-branes by forming a fuzzy funnel.

Solution:
$$X^{\mu} = r(s)G^{\mu}$$

$$r(s) = \frac{1}{\sqrt{s}} \; , \; G^{\mu} = \varepsilon^{\mu\nu\rho\sigma} [G^{\nu}, G^{\rho}, G^{\sigma}]$$

Matches profile from SUGRA analysis

The M2-branes form a fuzzy funnel:

 G^{μ} form a rep of $\mathfrak{so}(4)$: coordinates on fuzzy sphere S_F^3

M2-worldvolume polarizes: $3d \rightarrow 6d$

- 3-form structure appears
- quantization of S³ required.

Further Motivation

There are more appearances of 2-plectic manifolds in string-/M-theory.

M5-brane perspective: Turning on 3-form background,

$$C = \theta dx^0 \wedge dx^1 \wedge dx^2 + \theta' dx^0 \wedge dx^1 \wedge dx^2,$$

the self-dual strings move in $\mathbb{R}^{1,2}_{\lambda} imes \mathbb{R}^{3}_{\lambda'}$ with

$$[x^0,x^1,x^2]=\lambda \quad \text{and} \quad [x^3,x^4,x^5]=\lambda' \; .$$
 Chu, Smith, 0901.1847

• Using T-duality, Lüst, 1010.1361, conjectured that closed strings on T^3 in 3-form background lead to:

$$[x^i,x^j]\sim \varepsilon^{ijk}p_k$$
 , $[x^i,p_j]\sim \delta^i_j$, $[p_i,p_j]\sim \varepsilon^{ijk}p_k$.

Note that here, the Jacobi identity is not satisfied.

Outline

- Quantization axioms for 2-plectic manifolds
- Quantized 2-plectic manifolds as vacua of 3-algebra models
- Another approach: Quantization via Groupoids

Axioms of Quantization

Quantization is nontrivial and far from being fully understood.

Classical level: states are points on a Poisson manifold \mathcal{M} .

observables are functions on \mathcal{M} .

Quantum level: states are rays in a complex Hilbert space ${\mathscr H}$.

observables are hermitian operators on ${\mathscr H}.$

Full Quantization

A full quantization is a map $\hat{-}:\mathcal{C}^{\infty}(\mathcal{M})\to \operatorname{End}\left(\mathscr{H}\right)$ satisfying

- $oldsymbol{0} f \mapsto \hat{f}$ is linear over \mathbb{C} , $f = f^* \Rightarrow \hat{f} = \hat{f}^\dagger$.
- ② the constant function f=1 is mapped to the identity on ${\mathscr H}.$
- **3** Correspondence principle: $\{f_1, f_2\} = g \Rightarrow [\hat{f}_1, \hat{f}_2] = \hat{g}$.
- $oldsymbol{0}$ The quantized coordinate functions act irreducibly on \mathscr{H} .

Problem:

Groenewold-van Howe: no full quant. for $T^*\mathbb{R}^n$ or S^2 $(T^2 \ \mathsf{OK})$

Loopholes to the obstructions to full quantizations. There are three possible weakenings to the set of axioms for quantization.

Three approaches to weaken the axioms of a full quantization:

- Drop irreducibility condition
- Quantize a subset of $\mathcal{C}^{\infty}(\mathcal{M})$
- Correspondence principle applies only to $\mathcal{O}(\hbar)$

The first two yield prequantization and geometric quantization. The last approach leads eventually to deformation quantization.

My favorite method for this talk: Berezin quantization (or fuzzy geometry for physicists), a hybrid of geometric and deformation quantization.

Berezin Quantization of $\mathbb{C}P^1 \simeq S^2$ The fuzzy sphere is the Berezin quantization of $\mathbb{C}P^1$.

Hilbert space

 \mathscr{H} is the space of global holomorphic sections of a certain line bundle: $\mathscr{H} = H^0(\mathcal{M}, L)$. For $\mathcal{M} = \mathbb{C}P^1$: $L := \mathcal{O}(k)$. $\mathscr{H}_k \cong \operatorname{span}(z_{\alpha_1}...z_{\alpha_k}) \cong \operatorname{span}(\hat{a}_{\alpha_1}^{\dagger}...\hat{a}_{\alpha_k}^{\dagger}, |0\rangle)$

Coherent states

For any $z \in \mathcal{M}$: coherent st. $|z\rangle \in \mathcal{H}$. Here: $|z\rangle = \frac{1}{k!}(\bar{z}_{\alpha}\hat{a}_{\alpha}^{\dagger})^{k}|0\rangle$.

Quantization

Quantization is the inverse map on the image $\Sigma = \sigma(\mathcal{C}^\infty(\mathcal{M}))$ of

$$f(z) = \sigma(\hat{f}) = \, \mathrm{tr} \, \left(\frac{|z\rangle \langle z|}{\langle z|z\rangle} \hat{f} \right) \; , \quad \mathsf{Bridge:} \; \mathcal{P} := \frac{|z\rangle \langle z|}{\langle z|z\rangle}$$

Axioms of Generalized Quantization

We propose a generalization of the quantization axioms to p-plectic manifolds.

Problem is notoriously difficult, and many people tried to extend geometric quantization. Berezin quantization should be easier. Keep: a complex Hilbert space $\mathscr H$ and $\operatorname{End}(\mathscr H)$ as observables.

Generalized quantization axioms

A full quantization is a map $\hat{-}:\Sigma\to \operatorname{End}(\mathscr{H}),\ \Sigma\subset\mathcal{C}^\infty(M)$ satisfying

- $oldsymbol{0} f \mapsto \hat{f}$ is linear over \mathbb{C} , $f = f^* \Rightarrow \hat{f} = \hat{f}^\dagger$.
- ② the constant function f=1 is mapped to the identity on \mathcal{H} .
- 3 Correspondence principle:

$$\lim_{\hbar \to 0} \left\| \frac{\mathrm{i}}{\hbar} \, \sigma \left([\hat{f}_1, \dots, \hat{f}_n] \right) - \{ f_1, \dots, f_n \} \right\|_{L^2} = 0$$

If \mathcal{M} is a Poisson manifold, this holds for Berezin quantization.

Quantization of \mathbb{R}^3

The quantized Nambu-Heisenberg algebra corresponds to the space \mathbb{R}^3_λ .

We start from \mathbb{R}^3 with $\omega = \varepsilon_{ijk} \mathrm{d} x^i \wedge \mathrm{d} x^j \wedge \mathrm{d} x^k$.

We find
$$\{f,g,h\}= \varepsilon^{ijk} \frac{\partial}{\partial x^i} f \frac{\partial}{\partial x^j} g \frac{\partial}{\partial x^k} h.$$

What is the geometry of $[\hat{x}, \hat{y}, \hat{z}] = -i \hbar \, \mathbb{1}$?

One possible interpretation as \mathbb{R}^3_{λ} :

Take a fuzzy sphere with Hilbert space $H^0(\mathbb{C}P^1,\mathcal{O}(k))$. Define:

$$[\hat{x}^1, \hat{x}^2, \hat{x}^3] = \sum_{i,j,k} \varepsilon^{ijk} \hat{x}^i \hat{x}^j \hat{x}^k = -\mathrm{i} \frac{6R^3}{k} \, \mathbb{1}_{\mathscr{H}_k}$$

Radius of this fuzzy sphere: $R_{F,k} = \sqrt{1 + \frac{2}{k}} \sqrt[3]{\frac{\hbar k}{6}}$. Now "discretely foliate" \mathbb{R}^3 by fuzzy spheres. $\Rightarrow \mathbb{R}^3$.

Brief Review: The IKKT model

Noncommutative geometries arise as stable solutions of the IKKT matrix model.

Fully dimensionally reduce maximally SUSY Yang-Mills theory:

$$S = \, \operatorname{tr}\,([X^I,X^J][X_I,X_J] + \mu_I(X^I)^2 + C_{IJK}X^I[X^J,X^K] + \operatorname{fermions})$$

where $X^I \in \mathfrak{u}(N)$, $I = 0, \dots, 9$. Stable classical solutions:

$$\begin{array}{lll} \text{Moyal spaces} & \mu_i = C_{ijk} = 0 & [X^i, X^j] \sim \theta^{ij} \mathbb{1} \\ \hline \text{Fuzzy sphere} & C_{123} = 1 & [X^i, X^j] \sim \varepsilon^{ijk} X_k \\ \hline \text{NC Hpp-waves} & C_{123} = 1, \ \mu_1 = \mu_2 = \mu & [X^1, X^2] \sim \theta^{12} \mathbb{1} \\ & [X^3, X^i] \sim \theta^{ij} X^j \\ \hline \end{array}$$

First two: BPS. The third: Nappi-Witten algebra.

Hpp-waves: 4d Cahen-Wallach symm. space in Brinkman coords.:

$$ds_4^2 = 2\alpha \beta dx^+ dx^- + \gamma^2 |dz|^2 - \frac{1}{4} \beta^2 (\gamma^2 |z|^2 - b) (dx^+)^2$$

Identification:

$$X^1 + iX^2 \sim z$$
, $X^3 \sim J$, $X^4 \sim 1$.

The dimensionally reduced BLG model

The theory corresponding to SYM is the BLG model, which we dimensionally reduce.

Basu-Harvey \rightarrow Bagger, Lambert and Gustavsson developed a Chern-Simons matter theory for M2-branes. Reduced form:

$$\begin{split} S &= -\frac{1}{2} \left(A_{\mu} X^{I}, A^{\mu} X^{I} \right) + \frac{i}{2} \left(\bar{\Psi}, \Gamma^{\mu} A_{\mu} \Psi \right) - \frac{1}{2} \sum_{I=1}^{8} \mu_{1,I}^{2} \left(X^{I}, X^{I} \right) \\ &+ \frac{i}{2} \mu_{2} \left(\bar{\Psi}, \Gamma_{3456} \Psi \right) + C^{IJKL} \left([X^{I}, X^{J}, X^{K}], X^{L} \right) \\ &+ \frac{i}{4} \left(\bar{\Psi}, \Gamma_{IJ} [X^{I}, X^{J}, \Psi] \right) - \frac{1}{12} \left([X^{I}, X^{J}, X^{K}], [X^{I}, X^{J}, X^{K}] \right) \\ &+ \frac{1}{6} \epsilon^{\mu\nu\lambda} \left(\left(A_{\mu}, [A_{\nu}, A_{\lambda}] \right) \right) + \frac{1}{4\gamma^{2}} \left(\left([A_{\mu}, A_{\nu}], [A^{\mu}, A^{\nu}] \right) \right) . \end{split}$$

Matter fields X^I , Ψ in vector space forming an orth. rep. of the gauge algebra in which A_μ lives. ("3-Lie algebra")

This model should take over the role of the IKKT model!

Solutions in the 3-Lie algebra model

Stable solutions of the IKKT model have a 3-Lie algebra analogue.

Stable classical solutions:

First two solutions again BPS. The third: 5d Hpp-wave backgrnd.:

$$ds_4^2 = 2\alpha \beta dx^+ dx^- + \gamma^2 |\vec{dz}|^2 - \frac{1}{4} \beta^2 (\gamma^2 |\vec{z}|^2 - b) (dx^+)^2$$

Identification:

$$X^{1} + iX^{2} \sim z$$
, $X^{3} \sim z^{3}$, $X^{4} \sim J$, $X^{5} \sim 1$.

Also: IKKT expanded around solution: NC YM theory on solution. 3-algebra model expanded around solutions: expected part + ...

The groupoid approach to quantization

The elements of geometric quantization can be written in a groupoid language.

Groupoids: Objects + composable, invertible arrows between them.

Why groupoids?

- Quantization of the dual of a Lie algebra:
 Twisted convolution algebra of integrating group
- ullet Poisson struct. o Lie algebroid o Conv. alg. on Lie groupoid
- Construction avoids Hilbert spaces, useful for 2-plectic case

Procedure (Eli Hawkins, math/0612363, Weinstein, Renault, ...)

- **1** Integrating groupoid $s, t : \Sigma \rightrightarrows M$, ω , $\partial^* \omega = 0$, t Poisson
- **2** Construct a prequantization of Σ with data (L, ∇)
- **3** Endow Σ with a groupoid polarization
- Construct a twist element
- **1** Obtain twisted polarized convolution algebra of Σ .

Example: Groupoid quantization of \mathbb{R}^2

The Moyal plane is conveniently reproduced in groupoid language.

Starting point: $M = \mathbb{R}^2$, Poisson structure π^{ij} , i, j = 1, 2.

 $\textcircled{1} \ \, \text{Lie groupoid:} \ \, \Sigma = M \times M^* \text{, coords.} \, (x^i,y_i) \text{, } \omega = \mathrm{d} x^i \wedge \mathrm{d} y_i$

$$s(x^i, y_i) = (x^i + \frac{1}{2}\pi^{ij}y_j)$$
 and $t(x^i, y_i) = (x^i - \frac{1}{2}\pi^{ij}y_j)$

Note: t is indeed a Poisson map: $\{t^*f, t^*g\}_{\omega} = t^*\{f, g\}_{\pi}$

$$x^i + \pi^{ij}(y_j + y'_j) \longrightarrow x^i + \pi^{ij}(y_j - y'_j) \longrightarrow x^i - \pi^{ij}(y_j + y'_j)$$

From this: pr_1 , pr_2 and m. $\partial^*\omega=p_1^*\omega-m^*\omega+p_2^*\omega=0$

- 2 Prequantization: L trivial line bundle over Σ , $F=-\mathrm{i}2\pi\omega$
- **3** Polarization: Induced by symplectic prepotential $\theta = -x^i dy_i$
- Twist element: $\partial^* \theta = \sigma_0^{-1} d\sigma_0 = d(-\frac{1}{2}\pi^{ij}y_iy_j')$
- ullet Twisted polarized convolution algebra: Moyal product on M

Hawkins

Groupoid quantization of \mathbb{R}^3

The groupoid approach can be extended to higher structures using loop space.

Starting point: $M = \mathbb{R}^3$, Poisson structure $\pi^{ijk}\dot{x}_k$, i, j = 1, 2.

• Lie groupoid: $\Sigma = LM \times LM^*$, coords. (x^i, y_i) , $\omega = \mathrm{d}x^i \wedge y_i$

$$s(x^i,y_i) = (x^i + \tfrac12 \pi^{ijk} y_j \dot x_k) \quad \text{and} \quad t(x^i,y_i) = (x^i - \tfrac12 \pi^{ijk} y_j \dot x_k)$$

Note: t is indeed a Poisson map: $\{t^*f, t^*g\}_{\omega} = t^*\{f, g\}_{\pi}$

$$x^{i} + \pi^{ij}(y_{j} + y'_{j})\dot{x}_{k} \to x^{i} + \pi^{ijk}(y_{j} - y'_{j})\dot{x}_{k} \to x^{i} - \pi^{ijk}(y_{j} + y'_{j})\dot{x}_{k}$$

From this: pr_1 , pr_2 and m. $\partial^*\omega=p_1^*\omega-m^*\omega+p_2^*\omega=0$

- 2 Prequantization: L trivial line bundle over Σ , $F=-\mathrm{i}2\pi\omega$
- **3** Polarization: Induced by symplectic prepotential $\theta = -x^i dy_i$
- Twist element: $\partial^* \theta = \sigma_0^{-1} d\sigma_0 = d(-\frac{1}{2}\pi^{ijk}y_i y_j' \dot{x}_k)$
- **1** Twisted polar. conv. alg.: $[x^i(\tau), x^j(\sigma)] = \delta(\tau \sigma)\pi^{ijk}\dot{x}_k(\tau)$

Summary:

- √ Naive approach to quantizing 2-plectic manifolds works OK
- ✓ IKKT-like model can be written down, has expected features.
- √ Groupoids offer a more general approach to quantization

Future directions:

- Extend groupoid constructions to other spaces.
- ▶ Unify picture: Higher Poisson structures? Courant algebroids?

Quantization of 2-plectic Manifolds

Christian Sämann

School of Mathematical and Computer Sciences Heriot Watt University, Edinburgh

EU-NCG 4th Annual Meeting, 29.4.2011
